ABSTRACT

In this paper, we present a strategy to provide users with explainable cross-domain recommendations (CDR) that exploits large language models (LLMs). Generally speaking, CDR is a task that is hard to tackle, mainly due to *data sparsity* issues. Indeed, CDR models require a large amount of data labeled in both *source* and *target* domains, which are not easy to collect. Accordingly, our approach relies on the intuition that the knowledge that is already encoded in LLMs can be used to more easily bridge the domains and seamlessly provide users with personalized cross-domain suggestions.

To this end, we designed a pipeline to: (a) instruct a LLM to handle a CDR task; (b) design a personalized prompt, based on the preferences of the user in a *source* domain, and a list of items to be ranked in *target* domain; (c) feed the LLM with the prompt, in both *zero-shot* and *one-shot* settings, and process the answer in order to extract the recommendations and a natural language explanation. As shown in the experimental evaluation, our approach beats several established state-of-the-art baselines for CDR in most of the experimental settings, thus showing the effectiveness of LLMs also in this novel and scarcely investigated scenario.

and Prompting Large Language Models for Explainable Cross-domain Recommendations. In *18th ACM Conference on Recommender Systems (RecSys '24)*, October 14–18, 2024, Bari, Italy. ACM, New York, NY, USA, 11 pages. <https://doi.org/10.1145/3640457.3688137>

1 INTRODUCTION

Recommender systems (RSs) have emerged as essential tools to support users in decision-making [39]. These systems leverage user preferences and historical behavior to suggest items of potential interest, ranging from movies and music to products and news articles [20]. Generally speaking, RSs employ various algorithms, including collaborative filtering, content-based filtering, and hybrid methods, to generate personalized recommendations tailored to individual users [40]. Cross-domain recommender systems (CDR) [10] represent a specialized class of RSs designed to address the challenge of recommendation in heterogeneous domains. Unlike traditional RSs, that operate within a single domain, cross-domain recommender systems extend their capabilities across multiple domains (typically referred to as *source* and *target* domains), accommodating diverse types of items and user preferences. By leveraging knowledge transfer and domain adaptation techniques [24], these systems enable the transfer of insights and recommendations from one domain to another. However, CDR typically suffer of *data sparsity* issues [6], since they require a large amount of labeled data in both the domains, which is not easy to collect. Moreover, some works [8] showed that the actual *transfer* of knowledge that happens between the domains is often over-claimed. A suitable solution is represented by content-based features and item metadata, whose exploitation in the area of RSs is largely established [30, 34]. As shown by several works, [12, 17], this information be used to better link the knowledge across the domains and provide accurate CDRs.

In this research direction, Large Language Models (LLMs) represent a promising means to provide CDRs with the knowledge that is needed to transfer preferences across different domains. Indeed, LLMs are trained on vast corpora of text data to learn complex patterns and relationships within language. These models, such as GPT [1, 54] and LLaMa [48, 49], excel at natural language understanding

and generation tasks, including machine translation [2, 7], summarization [25, 47], and dialogue generation [51]. While some attempts towards the exploitation of LLMs for recommendation tasks has been proposed [9, 15, 16], up to our knowledge the use of LLMs to tackle CDR tasks has been scarcely investigated. Conversely, in our conjecture, the huge amount of knowledge that is already encoded in LLMs can be used to more easily bridge the domains and seamlessly provide users with cross-domain suggestions.

Accordingly, this paper aims to fill in this gap by proposing a pipeline to: (a) instruct open LLMs to handle a CDR task; (b) design a personalized prompt, based on the preferences of the user in a *source* domain, and a list of items to be ranked in *target* domain; (c) feed the LLM with the prompt, in both *zero-shot* and *one-shot* settings, and process the answer to extract the recommendations together with a natural language explanation. As shown in the experiments, based on the comparison of three different state-of-the-art (SOTA) LLMs, *i.e.*, GPT, LLaMa and Mistral [1, 21, 48, 49, 54], our approach beats several baselines for CDR in most of the experimental settings, thus showing the effectiveness of LLMs also in this scarcely investigated scenario. To sum up, this paper provides the following contributions: (1) We introduce a pipeline that allows LLMs to handle a CDR task, based on instruction tuning techniques; (2) We design a strategy to prompt LLMs and obtain suitable CDRs, together with a natural language explanation; (3) We compare our approach to several baselines for CDR, and we guarantee the reproducibility of the protocol by releasing our source code.

The rest of the paper is organized as follows: in Section 2 we discuss related work. Next, Section 3 introduces the problem and Section 4 describes our workflow to obtain CDRs based on LLMs. Finally, in Section 5 we present our experiments, and in Section 6 we provide the conclusions and sketch future research directions.

2 RELATED WORK

In this section, we provide some basics of LLMs and we present an overview of RSs based on these models, by emphasizing the distinctive traits of our work.

2.1 Large Language Models

Large language models (LLMs) have revolutionized the landscape of artificial intelligence research, including RSs. These models, which put down roots in the area of distributional semantics [35], are typically based on Transformers [50] and are trained on huge amount of textual data. The hallmark of Transformers is the use of *attention mechanisms* to influence the representation of a piece of text based on the semantics of the (most relevant) surrounding words. This allows to learn representations that are very accurate and encode many nuances of the language [18]. Early LLMs, such as BERT [11], exploited the Transformers in the so-called *encoder-only* fashion, *i.e.*, the output of the process was an embedding representing word or sentences. Conversely, more recent models, such as GPT [1, 54], LLaMa [48, 49], T5 [37], and Mistral [21], rely on *encoder-decoder* or *decoder-only* architectures. In other terms, these LLMs can also generate textual content that is coherent to a generic input (*i.e.*, the answer to a question, or the completion of a sentence). Such a *generation* capability allowed LLMs to handle many and diverse

downstream tasks, including recommendations, and gave rise to systems such as ChatGPT.

In order to fully exploit the knowledge available in LLMs, it is necessary to *prompt* these models. Generally speaking, the concept of *prompt engineering* [5] refers to process of crafting specific instructions, called prompts, to guide a LLM towards a desired outcome. Based on the amount of information that is provided to the LLMs, prompting strategies can be roughly split into *zero-shot* and *one-shot* (or, more in general, *few-shot*) prompting. In the first case, the prompt itself contains all the necessary information for the LLM to complete the task. As an example, a zero-shot prompt for a recommendation task may just include the preferences of the user and the request for a list of suggestions. Conversely, in the latter case, also referred to as *in-context learning*, the prompt is accompanied by one or more examples that show the desired output, in terms of content, format and style. This extra information helps the LLM to better understand the task and return a correct output.

However, the effectiveness of prompting strategies often clashes with the number of parameters of the models. Indeed, huge models such as GPT3.5 or GPT-4 (consisting of approx. 175B and 1.8T of parameters¹, respectively) are able to effectively tackle very diverse tasks, even in zero-shot settings. Conversely, relatively smaller models, such as LLaMa (consisting of 7 or 13 billions of parameters), do not have sufficient generalization capabilities to be equally accurate. In these cases, before prompting a model it is often necessary to *specialize* them in the task to be tackled. This is done through an approach that is referred to as *fine-tuning*, which involves an additional training step of the LLM by injecting a set of new and labeled data that are specific to the task. When fine-tuning is used to let LLMs handle new tasks it was not originally trained on, this strategy is known as *instruction tuning* [56]. As regards training strategies, when re-training is too computationally expensive, strategies for parameter-efficient fine tuning (PEFT) such as LORA [19] and prompt tuning [26] can be exploited. These models either work on an approximation of the original weight matrices or learn a smaller portion of the original LLM. However, *it is necessary to point out that fine-tuning and instruction-tuning strategies can be only run on open-sourced LLMs, such as LLaMa.*

In this paper, we put together all the above mentioned pieces and we propose a framework based on LLMs to tackle a CDR task. This is done by first exploiting *instruction tuning* techniques to let LLMs adapt to our scopes. Subsequently, we explored *prompt engineering* to design a proper prompt that returns a list of recommendations together with an explanation. All the details will be provided next.

2.2 LLMs for Recommender Systems

While early attempts have exploited LLMs and Transformers as encoders [36, 46], recent works either use them by directly prompting for recommendations or by fine-tuning for the task.

As for fine-tuned models, the first attempt to jointly address recommendation tasks through LLMs is represented by P5 [16]. This model is based on T5 [37] and introduces different prompts to tackle different recommendation tasks, including rating prediction, sequential recommendation and so on. A similar attempt is

¹<https://the-decoder.com/gpt-4-architecture-datasets-costs-and-more-leaked/>

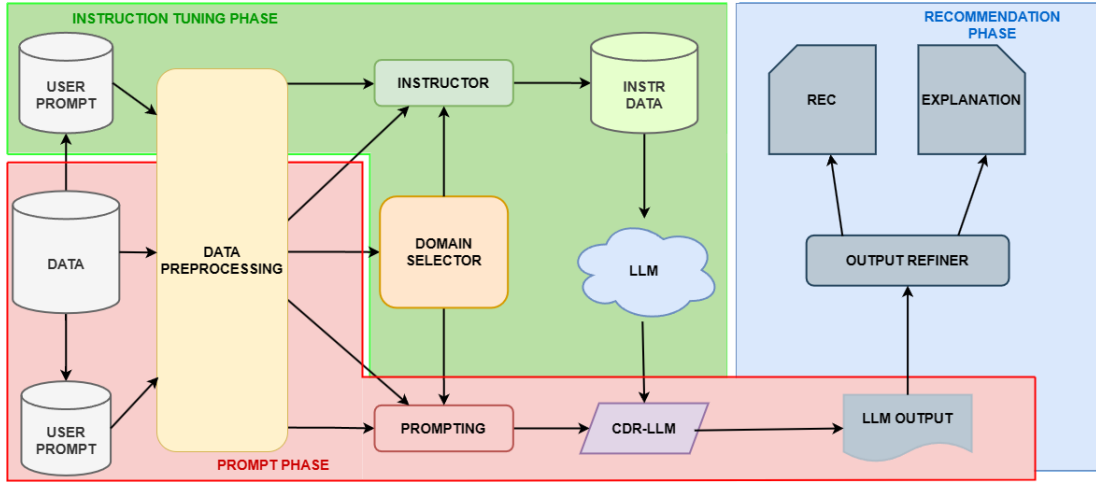

Figure 1: Workflow of the proposed model

proposed in M6-Rec [9], built on the M6 architecture [27]. While both these models obtained remarkable results, it was not possible to consider them as *baselines* since CDR is not among the tasks these models can handle. Moreover, our work is not directly comparable since we designed a *discrete* prompt where preferences are represented in a textual form, rather than using only item IDs.

Next, as regards models directly prompting LLMs to obtain recommendations, in [23] the authors evaluate models belonging to the GPT family [55]. This is done by feeding the LLM with a prompt representing the user profile based on their past item ratings. Even without fine-tuning, the model achieved performance comparable to baseline models. Another study [41] focused on sequential recommendation tasks, considering both item descriptions and user preferences. Their findings suggest that in-context learning outperforms the zero-shot approach. Finally, in [15] the authors propose a framework utilizing GPT for both rating and ranking prediction, showcasing remarkable capabilities in the movie domain.

While our approach shares with these works the idea of prompting LLMs for recommendations, **the novelty of this paper lies in the exploitation of LLMs for cross-domain recommendation, in both zero-shot and one-shot settings.** Up to our knowledge, this research direction has been never investigated in literature. **Moreover, we also used LLMs to generate an explanation supporting the recommendations.** With the exception of some early work [42], this direction is scarcely investigated as well.

3 PROBLEM FORMULATION

Unlike traditional RSs, CDR tasks involve two domains: a source domain \mathcal{D}_S and a target domain \mathcal{D}_T (i.e., movies and books). Let $\mathcal{I}_S = \{i_{1S}, \dots, i_{nS}\}$ and $\mathcal{I}_T = \{i_{1T}, \dots, i_{mT}\}$, be the sets of the items in the different domains. For each $i \in \mathcal{I}_S$ or \mathcal{I}_T we can assume that a list $\mathcal{F}_i = \{f_1, \dots, f_z\}$ of descriptive features of the item (i.e., genre, categories, author, etc.) exists.

Next, let $\mathcal{U}_S = \{u_{1S}, \dots, u_{jS}\}$ and $\mathcal{U}_T = \{i_{1T}, \dots, i_{kT}\}$, be the sets of the *users* who interacted with the items in the source and target domains, respectively. As regards the users, it is worth pointing

out that our evaluation will rely on the users who have provided positive ratings in *both* source and target domains². Formally, target users are represented by the overlapping set $\mathcal{U} = \mathcal{U}_S \cap \mathcal{U}_T$.

In our workflow, for each $u \in \mathcal{U}$, we first collect their positive and negative preferences. Let $\mathcal{P}_{u,S}$ and $\mathcal{N}_{u,S} \subseteq \mathcal{I}_S$ be the sets of the items liked and disliked by the user u in the *source* domain, and let $\mathcal{R}_{u,T} \subseteq \mathcal{I}_T$ be the set of the items to be ranked in the target domain, i.e., the ground truth. Given a generic LLM, we design a prompt that takes as input the items in $\mathcal{P}_{u,S}$, $\mathcal{N}_{u,S}$ and $\mathcal{R}_{u,T}$, together with their descriptive features \mathcal{F} , and returns as output a list $\tilde{\mathcal{R}}$ that re-ranks the items in $\mathcal{R}_{u,T}$. Formally:

$$\tilde{\mathcal{R}} = \text{prompt}(\text{LLM}, \mathcal{P}_{u,S}, \mathcal{N}_{u,S}, \mathcal{R}_{u,T}, \mathcal{F}) \quad (1)$$

In the experiments, we assess to what extent $\tilde{\mathcal{R}}$ is close to the correct ranking of the items in $\mathcal{R}_{u,T}$, based on the ground truth.

4 METHODOLOGY

The workflow carried out by our strategy is presented in Figure 1. As shown in the Figure, it can be roughly split into four phases: (a) **data pre-processing**, whose goal is to prepare the data in a form that is suitable by a LLM; (b) **instruction tuning**, that uses a portion of the data to train the model to correctly tackle a CDR task; (c) **prompting**, that aims at building the natural language request for the LLM; (d) **refinement and recommendation**, where the output of the LLM is processed in order to extract the list of suggestions together with the explanations.

4.1 Data Pre-Processing

The first step that is carried out is the data pre-processing. In particular, this step takes as input all the data that are available (regardless of belonging to the *source* or *target* domains) and prepares them in a form that is suitable by our workflow. A fundamental preliminary step is the split of the set \mathcal{U} , defined as in Section 3, in two disjoint

²While this is not a requirement for a *real* CDR settings, in our scenario it becomes mandatory since we need ground truth data, i.e., items evaluated by the user in the target domain, to evaluate the accuracy of the recommendations.

subsets \mathcal{U}_I and \mathcal{U}_P . In particular, \mathcal{U}_I will be used for the *instruction tuning* step, while \mathcal{U}_P will be used for the *prompting* phase. It is important to point out that $\mathcal{U}_I \cap \mathcal{U}_T = \emptyset$. This design choice prevents *information leakage* and ensures a fair and unbiased evaluation of the model, since we guarantee that the users used to instruct the model are not used to evaluate the model itself³. Moreover, for each user u in either \mathcal{U}_I and \mathcal{U}_P , the sets $\mathcal{P}_{u,S}, \mathcal{N}_{u,S}, \mathcal{R}_{u,T}$ are built for every source and target domains. Finally, the set \mathcal{F} containing of the descriptive features of the items is obtained. As previously stated, all these sets represent the *input* of the LLM, in both the instruction tuning and prompting phases.

4.2 Instruction Tuning

As we stated throughout the paper, the goal of *instruction tuning* is to specialize a LLM to tackle new tasks. In our case, we provide a LLM with data regarding CDR scenarios, and we adapt the model. The output of this step is a new LLM, that is specialized on CDRs. From now on, we will refer to the model as CDR-LLM.

In a nutshell, the INSTRUCTOR model transforms the data coming from the pre-processing step in a form that is suitable by a LLM, and uses them to fill in a set of *adaptation prompts*, i.e., prompts that are used to adapt the LLM to new tasks, before fine-tuning again the model. In our case, we design a *discrete* prompt, i.e., we lexicalize all the information regarding the task, the preferences of the user and the features of the items as a *string*, and we concatenate all of them. To this end, the process is further split into two steps: first, the structure of the adaptation prompt is designed. In particular, the prompt is organized in three main parts: **System Prompt**. This part provides general instructions about the CDR task and the domains. **User Prompt**. This part details the user interaction history. It is further divided into three parts: (a) *User-liked items* in the source domain, with their features. (b) *User-disliked items* in the source domain, along their features. (c) *Candidate items* in the target domain, along their features. **Model Output**. This specifies the expected output for the LLM, which is the list of re-ranked candidate items in the target domain based on user preferences and an explanation of the provided recommendations.

Then, these parts are concatenated one to each other. Formally:

$$prompt_{adapt} = \text{SystemPrompt} \oplus \text{UserPrompt} \oplus \text{ModelOutput} \quad (2)$$

Where \oplus indicates concatenation. Once the structure of the prompt has been defined, each prompt can be filled in based on the information about user preferences and item features. A complete example of prompt is provided in Table 1.

As shown in the example, the **System Prompt** part remains *static*, while the **User Prompt** is dynamically populated based on the lexicalization of the preferences. Finally, the **Model Output** contains the correct ranking based on the ground truth and an explanation generated by the LLM itself. In other terms, the goal of the adaptation prompts is to provide LLMs with a description of the task together with a set of examples that also contain the *correct* answer the LLM should be able to provide, i.e., the correct ranking and a suitable explanation. In this way, we let the LLM exploit its

outstanding generalization capabilities and adapt its behavior to such a new and unseen task, even with a few number of examples.

This process is repeated for all the users in \mathcal{U}_I and over all the combinations of source and target domains. This choice is justified by the fact that we want to specialize the model in a *general* cross-domain recommendation task, regardless of the specific source and target domains. Conversely, as we will show in the next step, in the *prompting* phase a specific couple of source and target domains is picked, since we want to provide CDRs in a specific setting.

Once all the adaptation prompts are generated, our Instruction Data (see Figure 1) are obtained. Such data are used to fine-tune the model and output our CDR-LLM model. As regards this phase, we opted for a *full parameter fine-tuning* of the model. More details about this will be provided next. In particular, the objective of instruction tuning is to minimize the average loss over the entire set of instruction data defined as:

$$\min_{\theta \in \theta_{LLM}} \frac{1}{N} \sum_{i=1}^N L(LLM(p_i; \theta), r_i) \quad (3)$$

where p_i is an adaptation prompt (system and user parts), r_i is the expected response (the instruction output), L is a loss function, (generally the Cross Entropy), θ represents the parameters of the LLM model, and θ_{LLM} is the parameter space. In other terms, by minimizing this loss function, LLMs learn to accurately respond to novel and unseen prompts.

4.3 Prompting LLMs for CDR

Once the CDR-LLM model has been learnt, it is possible to prompt the model to return a list of CDRs based on the preferences of a user. As shown in the workflow, the prompting starts with the DOMAIN SELECTOR component, whose goal is to simply pick a *source* and a *target* domain to be used. Next, given the domains, for each user u in \mathcal{U}_P we build the sets $\mathcal{P}_{u,S}, \mathcal{N}_{u,S}, \mathcal{R}_{u,T}$, and we collect the descriptive features of the items. Next, we feed CDR-LLM with a personalized prompt based on these sets. In this case, the prompt follows the same structure presented in Table 1, with the exception of the model output, which is not provided. Indeed, in this case the answer will be obviously generated by the model. Formally,

$$prompt_{test} = \text{System Prompt} \oplus \text{User Prompt} \quad (4)$$

In other terms, in this step we simply prompt the LLM we have previously specialized, and we check to what extent it is able to provide accurate CDRs. It is important to emphasize again that the users in \mathcal{U}_P are completely disjoint from those in \mathcal{U}_I . Moreover, in order to also assess the effectiveness of *in-context learning* in cross-domain recommendations, we repeated the process in a *one-shot* setting i.e., we extended the user prompt by also adding an example of correct recommendation and explanation based on the profile of *another* user in \mathcal{U}_P . Due to space reasons, we cannot provide an example of this prompt. However, in the experiments we will compare the behavior of each LLM in both the settings.

4.4 Output Refinement and Recommendation

Despite the instruction tuning phase, the output of CDR-LLM may not always strictly follow the desired format. To address this, we

³Once the model has been fine-tuned, it is not necessary to repeat this step for every run. It is mandatory only when instruction tuning has to be carried out.

Instruction Input	
System prompt	You are a cross-domain recommender system User provides you a list of items from a source domain that they liked and a list of items such source domain that they disliked Using the same format as the user, you must re-rank the candidate items based on the user liked items and return the <i>top k</i> <i><target domain></i> Answer using the format: \n Items ranking: <list of top <i>k</i> recommended <i><domain></i> ids>. \n Explanation: <explanation>.
User prompt	I liked these books: Title: The Great Gatsby Brand: F. Scott Fitzgerald Categories: [Classic Literature, Fiction] Title: Harry Potter and the Philosopher's Stone Brand: J.K. Rowling Categories: [Fantasy, Young Adult] Instead, I disliked these books: Title: Fifty Shades of Grey Brand: E.L. James Categories: [Romance, Erotic Fiction] Title: Twilight Brand: Stephenie Meyer Categories: [Fantasy, Romance] Rank and return the top <i>k</i> movies from: Id: 1234 Title: The Great Gatsby Brand: Warner Bros. Pictures Categories: [Drama, Romance] Id: 5678 Title: Harry Potter and the Sorcerer's Stone Brand: Warner Bros. Pictures Categories: [Fantasy, Adventure] Id: 91011 Title: Gone Girl Brand: 20th Century Fox Categories: [Mystery, Thriller]
Instruction Output	
Model Output	Items ranking: 1234, 5678, 91011 Explanation: Based on the user's liked books, which include "The Great Gatsby" and "Harry Potter and the Philosopher's Stone", it's apparent that they enjoy classic books with elements of fiction and fantasy, particularly in the young adult genre.

Table 1: A complete example of prompt zero-shot setting.

introduced in our workflow an OUTPUT REFINEMENT step that guarantees the model's recommendations align with this format.

The refinement process consists of two steps. First, we analyze the IDs returned as output to avoid *hallucinations* [38] that are typical of LLMs. In particular, we compare the elements returned by CDR-LLM with those in $\mathcal{R}_u, \mathcal{T}$, and we filter those that did not occur in the original set of candidate items. Then, the final recommendation list corresponds to the list of filtered IDs, in the same order they appeared in the response of the LLM. Next, the explanation section is analyzed. In this case, we extract all the text after the word "Explanation:" occurring in the answer of the LLM. As shown in Table 1, the natural language explanations generated by CDR-LLM represent another distinctive trait of the current approach. Indeed, they clearly show the remarkable ability of the LLMs to seamlessly exploit the huge body of knowledge they encode to identify patterns and connections between items belonging to different domains. In the experimental evaluation, we will also partially evaluate this aspect.

4.5 Discussion

In this section, we have presented our framework to provide users with CDRs based on LLMs. Before going into details of the experiments, it is necessary to point out the following aspects: (1) We designed a very general framework, that can be adapted to every LLM. Accordingly, in the evaluation we will compare several LLMs at the SOTA, by considering both *open* and *close* LLMs, as well as smaller and larger LLMs (in terms of parameters). This guarantees the solidity of our findings; (2) While the framework is described as a pipeline, it is not necessary (and, sometimes, even not possible) to run all the steps. Indeed, *instruction tuning* can be only run for *open-sourced* LLMs, such as LLaMa. Closed models such as those belonging to the GPT family can be only directly prompted, since it is not possible to fine-tune them. (3) While instruction tuning cannot be run for all the models, this does not jeopardize the outcomes of the experiments. Indeed, as we will show in the next section, the huge number of parameters of GPT (*i.e.*, 25x w.r.t. LLaMa) allows it to correctly handle a CDR task even without the adaptation step.

On the contrary, *instruction tuning* is mandatory for smaller models. Without this step, they do not show the capability of generating an answer in the correct format. (4) In our experiments, we run instruction tuning and prompting by considering *all* the features that are available for the items in the source and target domains. While we agree that this choice completely falls into the concept of *prompt engineering* and should be carefully considered, due to space reasons it was not possible to discuss and report more results. This analysis is left as future work.

5 EXPERIMENTAL EVALUATION

Our experiments were designed to answer the following research questions (RQs):

- **(RQ1)** How do different LLMs perform in the CDR task, in terms of accuracy, ranking, popularity bias and quality of explanations?
- **(RQ2)** What is the effect of *in-context learning* on the different metrics we compared?
- **(RQ3)** How does the performance of LLMs in the CDR setting compare to that of SOTA models?

5.1 Experimental Design

Datasets. Following prior works in the area of CDR [3, 52, 58], we conducted experiments on Amazon dataset⁴ [33]. These data are particularly suitable for CDR since they have overlapping users across multiple domains. Specifically, we selected three datasets, *i.e.*, "Movies", "CDs", and "Books". Each item is provided with a title, a list of categories and an author and/or a brand. From these datasets, we generated six distinct cross-domain scenarios by interchanging their roles as either source or target domains. All these datasets have been preliminarily processed in order to filter out users having: (a) less than 5 preferences; (b) less than 10 items in the ground truth; (c) More than 30 items, in either training or test sets. The first heuristic was set to remove non-significant users. The second was necessary to obtain significant results (we used $k = 5$ as cut-off

Table 2: Statistics of the Datasets

for our metrics). Finally, the third heuristic was due to the limits in the length of the prompts (4096 tokens at most) that characterize current LLMs. Statistics of the datasets are provided in Table 2. All the datasets are released on our repository⁵.

Protocol. To run *instruction tuning*, we picked 5,642 users. Users were randomly selected, as long as the proportion among the different scenarios is guaranteed. The remaining users were used to test the framework in the prompting phase. To prepare the prompts, we established that items rated with a score of 5 out of 5 were considered as *positive*, while all the others were considered as *negative*. This guarantees a more balanced distribution of ratings. As we anticipated throughout the paper, to generate the recommendations we followed the *TestRatings* strategy [4], *i.e.*, we asked the LLM to re-rank the items in the test set, and we returned as recommendation the list of *top-k* items ranked by the LLM, by filtering out non-existing items and hallucinations (see Section 4.4).

Evaluation metrics. The recommendation lists have been evaluated through the ClayRS framework [31], ensuring reproducibility and repeatability. We considered Precision, Recall, F1, nDCG as *accuracy* metrics, as well as the average popularity of the recommended items. Additionally, we evaluate *explanation quality* using perplexity score⁶. This metric reflects the model’s uncertainty in predicting the next word in a textual output, *i.e.*, the explanations, in our case. A lower perplexity score indicates that the model is more confident in the generated text, suggesting a more coherent and well-structured explanation. Finally, for each metric, we assessed statistical significance by running *t-test*. Also in this case, we used the implementation available in ClayRS and we compared the scored obtained by each user for each metric.

Implementation Details. To run our experiments, we compared the performance of three SOTA LLMs. As regards GPT, we exploited GPT3.5 Turbo by using GPT’s APIs⁷. Next, we exploited LLaMa2-7B-chat⁸ for LLaMa, while Mistral-7B Instruct v0.2⁹ was used as reference model for Mistral. In the *instruction tuning* step, we fine-tuned these models for 15 training epochs and a batch size of 64. This was distributed as 16 instances per device across 4 Nvidia A100 GPUs using DeepSpeed [44]. We employed the Adam optimizer with a learning rate of 5e-5, weight decay of 1e-4, and a maximum gradient norm of 1.0. The training time per model was approximately 3 hours. As previously stated, instruction tuning was only possible for *open* LLMs such as LLaMa and Mistral.

Baselines. We evaluate the effectiveness of our proposed methods by comparing them with several competitive baselines available in RecBole [57]. In particular, we considered:

- (1) **EMCDR** [32]: This method utilizes a multi-layer perceptron to capture non-linear relationships across domains, enabling flexible learning of domain-specific features.
- (2) **BiTGCF** [28]: This approach relies on graph collaborative filtering and tackles data sparsity by leveraging domain knowledge and facilitating knowledge transfer between domains. It incorporates feature propagation to capture high-order connectivity in user-item graphs.
- (3) **DeepAPF** [53]: This attention-based CDR method learns non-uniform importance weights for both cross-domain commonalities and domain-specific user interests.
- (4) **CMF** [43]: This method introduces a relational learning architecture that performs simultaneous matrix factorization on multiple user-item relationships. Crucially, it shares latent factors across these matrices when users participate in multiple domains, allowing information from one domain to enhance prediction accuracy in another.
- (5) **CLFM** [14]: This method considers the diversity among related domains and incorporates both common and domain-specific rating patterns through joint non-negative matrix tri-factorization, enabling learning of shared patterns across domains while preserving domain-specific information.
- (6) **SSCDR** [22]: This method employs a semi-supervised mapping approach, learning latent vectors for users and items in each domain and then training a cross-domain mapping function using labeled data from overlapping users and unlabeled data from all items;

As regards the choice of the baselines, it is necessary to point out that we limit our comparison to the CDR models available in RecBole. This was done to guarantee a fair comparison and the reproducibility. Moreover, as regards potential baselines based on LLMs, methods such as P5 [16] and M6-Rec [9] were not considered since they did not support CDR. No other methods for CDR based on LLMs were found.

5.2 RQ1: Comparing LLMs for CDR

To answer RQ1, we compared the effectiveness of different LLMs in the task of providing users with CDRs. Results are presented in Table 3, 4 and 5, showing the performance in the movies, books and cd domains, respectively. **The first important answer to RQ1 is that the results did not show a LLM clearly beating the others. On the contrary, the results show a connection between the best-performing LLM and the target domain.**

⁵https://github.com/petrucellialessandro/RecSys_2024_CDR_LLM

⁶<https://huggingface.co/docs/transformers/perplexity>

⁷<https://platform.openai.com/docs/models/gpt-3-5-turbo>

⁸<https://huggingface.co/meta-llama/LLaMa-2-7b-chat-hf/>

⁹<https://huggingface.co/mistralai/Mistral-7B-Instruct-v0.2>

Indeed, as regards the movie domain (Table 3), LLaMa2 consistently surpasses GPT and Mistral on multiple metrics. It achieves superior Precision@5, Recall@5, and F1@5. Notably, the best performance is obtained in the zero-shot setting, and this confirms the remarkable capability of LLM to quickly adapt to new downstream tasks, without any fine tuning. While this is not the focus of this contribution, it is also worth pointing out that zero-shot strategies also allow to implement more sustainable [45] and energy-efficient solutions. Another tendency that emerged from the experiments is the performance of Mistral in recommending less popular items compared to GPT and LLaMa2. It is worth to note that the findings are completely aligned regardless of the *source* domain which is considered, *i.e.*, books or cd. This means that LLMs have the ability of finding connections between the domains by relying on the knowledge that is already encoded in these models. This confirms our intuitions, showing that LLMs can be a suitable solution to bridge heterogeneous domains and provide users with CDRs.

Next, as regards the book domain, the best-performing model is GPT, which overcomes both LLaMa2 and Mistral in all the settings. Such a different behavior can be probably explained in the light of the different body of knowledge that is used to train such models. Indeed, as showed by recent studies [29], it is likely that a significant portion of the text which is used to train GPT-3 comes from (copyrighted) books. Accordingly, it is not surprising that in our setting such a knowledge can be effectively exploited to better provide book recommendations. Moreover, differently from what we noted for movie recommendations, the best performance are obtained in 1-shot settings. This means that GPT can better exploit the information provided through *in-context learning* and even improve the accuracy of the recommendation. This behavior is probably due to the huge amount of parameters encoded in GPT (25x w.r.t. to LLaMa2, as previously stated) that fosters the generalization and adaptation capability of such models, even without instruction tuning. Finally, as for CD recommendation, Table 5 shows that GPT and LLaMa emerged as best-performing LLMs, significantly overcoming Mistral. However, while GPT achieves the highest Precision@5, Mistral excels again in recommending less popular items. Finally, LLaMa2 maintains good performance across precision, recall, and ranking metrics.

To sum up, this experiment showed that the different LLMs obtain results that are generally comparable. However, an important finding lies in the connection between the knowledge encoded in the LLMs and the overall performance, **since models trained on a larger amount of data of a particular kind (*i.e.*, books on GPT) tend to have better performance on that particular domain.** While this outcome needs to be further investigated, such behavior can be helpful to pick the most effective LLM for a particular task.

Another distinctive trait of our work lies in the generation of a natural language explanation supporting the recommendation. To this end, we evaluated the quality of the LLM-generated explanations based on perplexity values (see Table 6). These values provide insights into the clarity of explanations generated by the LLMs. Comparing perplexity values across different scenarios and LLMs, it is clear that Mistral consistently demonstrates lower perplexity compared to LLaMa2. Furthermore, within each LLM, the 1-shot scenario generally exhibits lower perplexity than the 0-shot scenario. **This is an interesting insight, showing that LLMs are**

able to improve the quality of the explanations they generate with just one example provided in the prompt. However, it is important to point out that perplexity measure the uncertainty or surprise of a language model in predicting a sequence of words. While lower perplexity generally corresponds to clearer explanations, it does not include other aspects such as coherence, relevance, or user satisfaction. Thus, although Mistral may have lower perplexity, it does not necessarily imply a *better* explanation. This is confirmed by analyzing the length of the explanations, since those based on Mistral are generally shorter in all the settings.

Accordingly, we also carried out a very preliminary qualitative analysis of the explanations generated by CDR-LLM. An example of explanations is provided in Table 8. As expected, while having lower perplexity, the explanations generated through Mistral tend to be very concise. Conversely, LLaMa2 showed a very interesting capability of improving the quality of the explanation by relying on the example provided in the prompt in the 1-shot setting. Finally, GPT provides very good explanations in both 0-shot and 1-shot scenarios. However, this is not surprising due the high number of parameters of the model. **To conclude, we can state that such a preliminary qualitative analysis showed that the explanations generated by our framework seem to effectively support the recommendations generated by CDR-LLM, finding the connections between source and target domains in an effective way.** A more precise analysis of the explanations, carried out through a user study, will be investigated in future work.

5.3 RQ2: Role of In-Context Learning

Next, to answer RQ2 we compared the performance of each LLM in the 1-shot setting w.r.t. the 0-shot setting. As regards GPT, results show that the introduction of in-context learning improved the accuracy of the recommendations, in terms of Precision, Recall and F1. As previously stated, this is not surprising since the huge amount of parameters of GPT allows this LLM to have a great generalization capability by just exploiting one single example. However, the use of examples tend to increase the popularity bias of CDR based on GPT. Conversely, the analysis of the results on LLaMa and Mistral led to more interesting results. In this case, a different behavior was noted for accuracy (*i.e.*, precision, recall, F1) and ranking metrics. As for the first, a decrease was noted. Conversely, the use of an example allows to increase the average NDCG of the models. Also in this case, the results can be explained in the light of the complexity of such models, which are significantly smaller w.r.t. GPT. As for accuracy metrics, it is likely that one single example is not enough to trigger generalization in LLaMa and Mistral. As future work, we will carry out further experiments with more input examples to support our conjecture. On the contrary, NDCG is positively impacted by the use of *shots*, since the nature of Transformers, which LLMs strongly rely on, is inherently *sequential*. Accordingly, while it is not surprising that a LLM need more information to learn how to *select* good items (as in precision, recall and F1), it is equally not surprising that a task that is closer to the principles of Transformers, *i.e.*, ranking, benefits more of the introduction of examples in the prompts. **Overall, this experiment showed that larger LLMs take more advantage from in-context learning.**

However, such a strategy has a positive impact on ranking and popularity bias on smaller LLMs as well.

Table 5: Result on Scenarios with CDs as Target Domain

5.4 RQ3: Comparison to Baselines

Finally, we compared CDR-LLM to several baselines in the area of CDR. Results are presented in 7. For each setting, the baselines are compared to the best-performing configuration emerged from RQ1.

As shown in the Table, our approach based on LLMs tend to outperform the baselines in most of the experimental settings. In particular, methods based on LLMs beat *all* the baselines on *all* the metrics for the CD-Movies, Movies-Books and Movies-CD setting, and most of the baselines in the Books-CD and CD-Books. Overall, in 4 out of 6 comparisons our framework got the best results in terms of Precision and F1, while in 5 out of 6 comparisons we obtained the best Recall. However, the most interesting findings regard the impact of our strategy in terms of ranking of the items. Indeed, we always obtained the best results in terms of NDCG (with

Table 7: Comparison of CDR baselines with LLM’s best result. Boldface metric indicates highest score. *: significantly better than all baselines with t-test $p < 0.05$.

Model	0-shot	1-Shot
LLaMa2	Based on the user's liked CDs, which include rock, progressive rock, and alternative rock genres, I have ranked the movies accordingly.	Based on the user's liked books, which include genres like literature & fiction, contemporary, and humor, I have recommended CDs that are related to the metal genre. This recommendation is made based on the assumption that the user's preference for literature & fiction and contemporary genres may align with the intense and energetic nature of metal music. Additionally, the recommendation includes CDs from bands like Iced Earth and Shadows Fall, which are known for their technical and progressive musical style, which might appeal to the user's interest in contemporary literature.
Mistral	Based on the user's liked and disliked movies, we can infer that the user has a preference for animation and children's books. Therefore, the recommended books are selected based on their categories.	Based on the user's liked movies, which include "Birdy VHS" and "Mean Streets VHS," it seems that the user has an interest in movies with a gritty and intense atmosphere. Therefore, I would recommend books that have a similar theme or tone.
GPT	Based on your liked books, which are mainly children's books and literature, I have recommended classical music albums that may resonate with the storytelling and emotional depth found in those genres. The recommended albums feature vocal performances and compositions that could evoke similar feelings to the narratives and themes present in the books you enjoyed.	Based on your liked books, which include a mix of fiction, humor, and biographies, the recommended movies are aligned with alternative rock and indie music genres, which often offer a diverse and unique storytelling experience through their lyrics and melodies. These recommendations aim to provide you with a creative and thought-provoking entertainment option that resonates with the variety in your reading preferences.

Table 8: Examples of explanations from LLMs for 0-shot and 1-shot recommendation tasks.

a statistically significant increase in 3 out of 6 scenarios). Finally, it is also remarkable the impact in terms of AveragePopularity. These results definitely confirm the effectiveness of our approach, since we showed that: (a) the sequential nature of Transformers is particularly suitable to tackle CDR as a ranking task, *i.e.*, to put the items in the right sequence, since it perfectly borrows the principles of Transformers to CDR. (b) the knowledge encoded in the LLMs, as well as the ability of finding non-trivial connections between items in the source and target domains leads to recommendations that are less prone to popularity bias. **Overall, the use of LLMs for CDR seem to be very promising in multi-objective fashion, since our recommendations showed a good trade-off between the quality of the rankings and their popularity bias. Moreover, the opportunity of generating a natural language explanation is another trait that supports the use of LLMs for CDR.**

6 CONCLUSIONS AND FUTURE WORK

In this paper, we have presented a framework for explainable CDR based on LLMs. Our framework first exploits instruction tuning to adapt LLMs to better handle a CDR task, then uses prompt engineering to ask a LLM return a list of recommendations together with a natural language explanation. Our experiments showed that our framework can provide results that often beat several SOTA baselines for CDR recommendations, and can also provide a suitable explanation that can make the CDR process more transparent. Moreover, results showed the importance of in-context learning, especially for ranking and explanation. As future work, we will analyze different strategies for optimization [13], instruction tuning and prompting, in order to better drive LLMs. Of course, we will also evaluate more LLMs and different domains.
